IN THE CLAIMS:

Please amend the claims as follows:

1. (Currently Amended) A method of controlling a data transmission memory (1) for the transmission of data packets between subscribers ~~T~~ in which a chained subscriber-pointer address list with address pointers for addressing data memory blocks of a data memory ~~(3)~~ is stored for each subscriber T in a pointer address memory ~~(2)~~, wherein each said data memory block comprises a plurality of data memory cells.

2-3. (Canceled)

4. (Previously Presented) The method as claimed in claim 1, in which, in a reception operating mode, reception data packets are received from various source subscribers via a reception data bus and are stored in data memory cells of a data memory block addressed by the subscriber-pointer address list.

5. (Currently Amended) The method as claimed in claim 1, in which, in a transmission operating mode, output data packets are in each case read out from a data memory block and sent to ~~the~~ an associated destination subscriber via an output data bus.

6. (Currently Amended) The method as claimed in claim ~~1~~ 4, in which each reception data packet contains destination information data for identifying ~~that~~ a destination subscriber for which the reception data packet is intended.

7. (Currently Amended) The method as claimed in claim 1, in which ~~the~~ a memory size of a data memory cell corresponds to the size of an input data packet and ~~the~~ a memory size of a data memory block preferably corresponds to the size of an output data packet.

8. (Currently Amended) The method as claimed in claim 1, in which ~~the~~ a state of each chained subscriber-pointer address list is stored in a subscriber state register ~~(12)~~.

9. (Currently Amended) The method as claimed in claim ~~1~~ 8, in which, in the subscriber state

register (12), a beginning address pointer to the last data block, the number of data memory blocks and the a filling level of the last data block are stored.

10. (Currently Amended) The method as claimed in claim 1, in which a pointer address list of the free pointer addresses is stored in the pointer address memory (2), so that the pointer address memory (2) forms a reproduction of the data memory (3).

11. (Currently Amended) The method as claimed in claim 1 6, in which, in the reception operating mode, the a last received reception data packet is written according to the a stored filling state into the a next free memory cell of the a last data memory block of the destination subscriber, identified by the reception data packet.

12. (Currently Amended) The method as claimed in claim 1 11, in which, after the reception data packet has been written into the last data memory block of the destination subscriber, the a filing state is incremented in the a associated state register (12).

13. (Currently Amended) The method as claimed in claim 1 8, in which the chained subscriber-pointer address list of the destination subscriber is extended by adding a chained address pointer for the addressing of a further data memory block if all the memory cells of the a last data memory block of the destination subscriber are filled after the a writing operation.

14. (Currently Amended) The method as claimed in claim 1, in which, in the a transmission operating mode, the a first date data memory block of the destination subscriber is sent as an output data packet.

15. (Currently Amended) The method as claimed in claim 1 14, in which, after the first data memory block has been sent, the chained subscriber-pointer address list of the destination subscriber is shortened by removing the a beginning address pointer, pointing to the first data block.

16. (Currently Amended) The method as claimed in claim 1, in which the a reception operating mode for writing reception data packets into the data transmission memory (1) has priority over the a

transmission operating mode for sending output data packets from the data transmission memory (1).

17. (Currently Amended) A data transmission memory (1) for the transmission of data packets between subscribers T with a pointer address memory (2) for storing chained subscriber-pointer address lists, comprising pointer addresses, for each subscriber; a plurality of subscriber state registers (12), which in each case store the state of an associated subscriber-pointer address list; a data memory (3) for storing data blocks which can be addressed by the pointer addresses; and with a memory controller (4) for controlling the pointer address memory (2) and the data memory (3).

18. (Currently Amended) The data transmission memory as claimed in claim 17, wherein the data memory (3) is a SRAM.

19. (Currently Amended) The data transmission memory as claimed in claim 17, wherein the pointer address memory (2) is an SRAM.

20. (Currently Amended) The data transmission memory as claimed in claim 17, wherein the memory controller (4) is connected to source subscribers via a reception data bus and to destination subscribers via a transmission data bus.

21. (Currently Amended) The data transmission memory as claimed in claim 17 20, wherein the transmission data bus and reception data bus are bidirectional buses for bidirectional data transmission.

22. (Currently Amended) The data transmission memory as claimed in claim 17 21, wherein the transmission data bus and reception data bus buses are Ethernet buses.
